one asset, one lien.

A NEUTRAL FIRST TO FILE LIEN REGISTRY ON CREDITCOIN · BUIDL CTC 2026 · RWA

Two lending protocols that never heard of each other will each lend against the same collateral, because neither can see what the other recorded. Singleton witnesses their pledges from the outside, through an inclusion proof re-checked by Creditcoin's BlockProver precompile, asks them for nothing, and refuses the second claim. It is UCC-9 first to file for on-chain collateral, without a trusted operator.

WHY IT CAN ONLY EXIST HERE

`LOG0` to `LOG4` are write only, receipts live in a trie execution never touches, and `BLOCKHASH` reaches back 256 blocks. So a neutral witness of somebody else's lending is either an off-chain indexer, which is a trusted party and therefore not neutral, or a contract that consumes an inclusion proof of that log. The second exists through BlockProver `0x0FD2` and nowhere else.

HOW ONE PLEDGE BECOMES A RECORD

01 THE PROTOCOL'S OWN LOG

A lender emits its native event. NFTfi and Blur Blend are read on Ethereum mainnet, unmodified and unaware.

02 THE PRECOMPILE

BlockProver verifies the proof inside the accepting transaction, past a depth read from ChainInfo `0x0fD3`. The registry checks the source receipt status itself, because the precompile does not.

03 THE REGISTER

First to file is recorded and given a soulbound certificate. Anything second reverts, and the refusal is kept on file for the next lender.

LIVE NOW, CHECKABLE WITHOUT ASKING US FOR ANYTHING

16
inclusion proofs on CC3 testnet, every hash published

2 / 2
attested source chains read, Sepolia and Ethereum mainnet

98
tests, both security reviews kept as regressions

0
wallets, backends or indexers between the page and the chain

THE DEMONSTRATION

Two tokenised deeds, two unrelated Sepolia lenders. On the first, a pledge is recorded, a second refused on chain as a failed transaction decoding to `AssetNotFree`, then settled, released and re-filed by the lender that lost the race. On the second, the refusal stays on file because that lien is never released. Six more proofs read real NFTfi and Blur Blend loans on mainnet, one ending in seizure after a failed auction. **Both mainnet protocols escrow**, checked on chain: they prove the reader works and cannot prove the fraud, which is why the collision is ours and why caveat 6 says so.

WHAT IT DOES NOT CLAIM

- **A positive record, not proof of absence.** Attestcoin proves a transaction happened, never that one did not.
- **The adapter is trusted for meaning, not existence.** Under a hundred and thirty lines of pure code each, named as semi-trusted before anybody asks.
- **Custody prevents this fraud mechanically**, and the non-custodial market for unique assets is empty. We read that as cause, not objection: lenders take possession because there is no register to check.

ATTESTCOIN PROTOCOL USE, STATED AS CALLS

BlockProver `0x0FD2` in its view form inside the accepting transaction; ChainInfo `0x0fD3` for the attested tip; AttestorStash `0x0FD4` for the bonded set behind that attestation, kept with every record and enforced as a floor; `EvmV1Decoder`; `@gluwa/usc-sdk`; and both attested source chains. The batch form of `verify` files many pledges from one continuity proof: four cost 1,582,616 gas filed singly and 989,237 filed together, 37.5 percent less. Most of that is a Creditcoin fact we measured, not read: code size is charged on every call, about 13 gas a byte. Replay protection is a nullifier per operation domain, keyed by chain, height, transaction index and log index. Every unused surface carries a written reason in `docs/SURFACES.md`.

TWO INDEPENDENT REVIEWS, ONE DAY, BOTH FOUND REAL BUGS

The first: a borrower could attach a decoy log carrying the registry's own event signature and make their genuine pledge permanently unregisterable. The second found the fix incomplete, because the emitter was still inferred from a receipt the borrower orders. The registry now searches for nothing: the relayer names the emitter and the log index and the registry only checks. A batch pledge became supported rather than refused, and mainnet gas fell from 716k to 634k. Both attacks are kept as regression tests, along with a corrected caveat that had claimed an administrator cannot fabricate, which was false.
